Charles R. Graves

CONTENTS

delayed and second growth occurred under these conditions. Several varieties were stunted at Knoxville where Temik had been used, especially if emergence was delayed due to crusting or slow germinating seed. The worst stunting occurred where the beans were covered with some soil from rotary hoeing to break the crust. Most varieties recovered and grew normally. TN 83-26 (an experimental) showed the most symptoms of Temik injury primarily of leaf crinkling. Forrest has shown the same symptoms under similar conditions where Temik has been used. Excellent soybean cyst nematode control was obtained at this location in 1986. In 1985 at Knoxville, where Furadan had been used, very little cyst nematode control was noted especially in some "hot" spots in the field.

In 1986 at Knoxville, Terra Vig 515, Pioneer brand 9591, Yield King 577, Hartz 5252, Hartz 5370, TN 5-85, and Forrest produced sixty or more bushels of beans.

Coker 425 is a high yielding, lodging resistant variety that seems to do better under good growing conditions. Due to its short growth habit without much lateral branching, it might respond to close row spacing. However, in wide rows under drought conditions, this variety's yields may be reduced more than other varieties due to its growth habit. At Greeneville in 1985 this variety grew taller and branched more than normal when compared with other locations in Tennessee.

The leading varieties in yield of Maturity group V were Terra Vig 515, Pioneer brand 9591, Deltapine 415, Deltapine 105, Coker 485, FFR 561 and Essex. Using a three-year average for this maturity group (V), Coker 485, Coker 425, Essex, FFR 561, Pioneer brand 5482, and Deltapine 105 were the highest yielding varieties (Table 5).

Thirty-two late-maturing varieties (Maturity group VI & VII) were evaluated at four locations in 1986 (Tables 7 and 8). No yield data are reported for Spring Hill due to late harvest; results will be published in another report.

The highest yielding varieties in this late group in 1986 were Coker 686, Coker 156, Asgrow A6520, Leflore, and Yield King 707. Jeff, Spartan, Yield King 707, Hartz 6383R and Yield King 757 had a tendency to lodge. The remaining varieties stood well in these studies in 1986. Using a two-year average (Tables 9 and 10), Asgrow A6242, Asgrow A6520, Leflore, Hartz 7126, and Shiloh yielded as well as or better than Centennial.

The early-maturing varieties of Maturity group IV or less were evaluated at five locations in 1986 (Tables 13 and 14). Yields at Springfield and Ames Plantation were reduced due to dry weather. RA 452, Pershing, and Bailey 469 produced the highest average yield for 1986.

Two strains tests were conducted at Jackson with 12 strains being evaluated in Maturity group V (Table 17) and 13 strains being evaluated in the late-maturity groups of VI & VII (Table 18). In Maturity group V at Jackson, TN 84-51 and TN 84-147 yielded as well as or better than Essex. In the late strain test, Hartz H81-9548 produced the highest average yield.

In 1986, Lawrence D. Young evaluated all varieties at Jackson in the greenhouse for susceptibility to soybean cyst nematodes (Tables 19 to 22). The susceptibility rating was based on a scale of 0, 1, 2, 3, and 4, with 4 being susceptible. A mean severity index was obtained by multiplying the rating times the number of plants with that rating, divided by the total number of plants.

Example 1: 8 plants with a rating of 4 = 32/8 = 4.0 mean severity index.

Example 2: (3 plants x 2 rating = 6) + (2 plants x 1 rating = 2) + (3 plants x 0 rating = 0) = 6 + 2 + 0 = 8 divided by 8 total plants = 1.0 mean severity index.

A letter rating was also given with R being resistant, S being susceptible, MR being moderately resistant and Seg. being a variety segregating for nematode resistance. A "+" was given when a variety had a rating greater than the worst rating of 4.
